## ABSTRACT

A nonlinear mathematical model has been formulated of a craft having a constant deadrise angle, planing in regular waves, using a modified low-aspect-ratio or strip theory. It was assumed that the wavelengths would be large in comparison to the craft length and that the wave slopes would be small. The coefficients in the equations of motion were determined by a combination of theoretical and empirical relationships. A simplified version for the case of a craft or model being towed at constant speed was programed for computations on a digital computer, and the results were compared with existing experimental data. Comparison of computed pitch and heave motions and phase angles with corresponding experimental data was remarkably good. Comparison of bow and center of gravity vertical accelerations was fair to good.

## ADMINISTRATIVE INFORMATION

This investigation was authorized by the Naval Sea Systems Command with initial funding under Task Area SR-023-0101 and completion under Task Area ZF-43-421001.

## INTRODUCTION

Computer programs for estimating the motions of displacement ships in waves for all headings and speeds have been in existence for some time. Comparable computational schemes for planing craft do not exist except in limited and restricted cases. A program for planing craft would be quite useful to the small craft designer, providing a means for systematically exploring the effects of numerous design variations on performance of the craft in waves. With minor modification, the program could also be used to examine the merits of a hybrid craft design, e.g., a combination of planing craft and hydrofoil.

Predicting the motions of a planing craft in wave's is by no means a simple problem. The analytical description of a high-speed craft, planing in waves, involves several different types of flow phenomena, including planing; hydrodynamic impact, and, to a lesser extent, surface wave generation and hydrostatics. Also, the mathematics tend to become nonlinear rapidly as the motion increases or, like the real craft, can in some instances exhibit large instabilities such as porpoising.

Development of a computer program that would take into account all of the previously described factors and would be applicable for a wide range of speed and wave conditions requires a careful and systematic study in several stages with appropriate verification at each stage. To lay the foundation for such a general program, a simpler problem has been

formulated in this report with potential for expansion and generalization to the more complicated case. The simpler problem is that of a V-shaped prismatic body with hard chines and constant deadrise planing at high speed in regular head waves.

The mathematical formulation is analogous to low-aspect-ratio wing theory with provisions for including hydrodynamic impact loads, essentially a strip theory. Surface wave generation and forces associated with unsteady circulatory flow are neglected, and the flow is treated as quasi-steady. The mathematical formulation is an empirical synthesis of several theoretically derived flows describing the overall craft hydrodynamics. Wave input is restricted to monochromatic linear deepwater waves with moderate wavelengths and low wave slopes.

## MATHEMATICAL FORMULATION

### GENERAL

Consider a fixed coordinate system ( $x, z$ ) (Figure 1) with  $x$  axis in the undisturbed free surface, pointing in the direction of craft travel, and the  $z$  axis, pointing downward. If the motions of the craft are restricted to pitch  $\theta$ , heave  $z_{CG}$ , and surge  $x_{CG}$ , the equation of motions can be written as

$$\begin{aligned} M\ddot{x}_{CG} &= T_x - N \sin \theta - D \cos \theta \\ M\ddot{z}_{CG} &= T_z - N \cos \theta + D \sin \theta + W \\ I\ddot{\theta} &= Nx_c - Dx_d + Tx_p \end{aligned} \quad (1)$$

where  $M$  is mass of craft

$I$  is pitch moment of inertia of craft

$N$  is hydrodynamic normal force

$D$  is friction drag

$W$  is weight of craft

$T_x$  is thrust component in  $x$  direction

$T_z$  is thrust component in  $z$  direction

$x_c$  is distance from center of gravity (CG) to center of pressure for normal force

$x_d$  is distance from CG to center of action for friction drag force

$x_p$  is moment arm of thrust about CG.

Equation (1) is exact; however, defining the hydrodynamic forces and moments in waves can be extremely difficult.

A high-speed craft moving in waves may transit through several regimes that have different hydrodynamic flow characteristics. For example, as the craft moves away from the crest of wave, the flow may be characterized by unsteady-state planing until the craft collides with the oncoming wave crest and enters another regime in which impact forces are important. After the impact, the craft may enter still another regime in which it is planing but in which buoyancy forces are rather significant.

The most promising approach to a method that would incorporate all three types of flow conditions into a general formulation would seem to be a modified strip theory. The mathematical justification for this approach is not rigorous; however, there is sufficient precedent to expect promising results. For example, impact loads on landing seaplanes can be estimated reasonably well using a strip theory incorporating the Wagner two-dimensional (2-D), expanding-wedge theory,<sup>1</sup> and Chuang<sup>2</sup> has provided a strip method for determining loads on an impacting prismatic form that agrees extremely well with experimental results.

More recently, Martin<sup>3</sup> has developed a linear strip theory for estimating motions of a planing craft at high speed, which shows good agreement with experimental results. A nonlinear model of the equations of motion would be expected to provide, in addition to the motions, reasonable estimates of the vertical accelerations which are an important consideration in designing a planing craft.

## TWO-DIMENSIONAL HYDRODYNAMIC FORCE

Implicit with any strip method is the need to define the 2-D hydrodynamic force acting on an arbitrary cross section of the body. The 2-D flow problem is not simple; however, it lends itself to an empirical approach, using a combination of techniques used in hydrodynamic impact and low-aspect-ratio theories.

The typical cross section of a hard-chine, V-shaped prismatic body such as that being considered here is shown in Figure 2. Figure 2 actually illustrates two different idealized-flow conditions, assumed to represent the crossflow during unsteady planing, depending upon whether the flow separates from the chine (Figure 2a) or not (Figure 2b). Nonwetted-chine flow conditions are typical of the sections near the leading edge of the wetted length of the craft. Wetted-chine flow conditions are more typical of sections near the stern, except possibly in the most extreme motion and wave conditions. Some sections between leading edge and stern may alternate between flow conditions as the wetted length changes with the motions.

---

\*A complete listing of references is given on page 33.

The normal hydrodynamic force per unit length  $f$ , acting at a section, is treated as quasi-steady and is assumed to contain components proportional to the rate of change of momentum and the velocity squared (drag term), i.e.

$$f = - \left\{ \frac{D}{Dt} (m_a V) + C_{D,c} \rho b V^2 \right\} \quad (2)$$

where  $V$  is the velocity in plane of the cross section normal to the baseline

$m_a$  is the added mass associated with the section form

$C_{D,c}$  is the crossflow drag coefficient

$\rho$  is the density of the fluid

$b$  is the half beam.

For sections near the leading edge of the wetted length with nonwetted chine, the added mass is assumed to be defined in the same manner as during an impact which for a V-shaped wedge is given by

$$m_a = k_a \pi/2 \rho b^2 \quad (3)$$

where  $k_a$  is an added-mass coefficient that may also include a correction for water pileup— $k_a$  is assumed to be 1.0 without pileup correction.

The rate of change of momentum of the fluid at a section is given by

$$\frac{D}{Dt} (m_a V) = m_a \dot{V} + V \dot{m}_a - \frac{\partial}{\partial \xi} (m_a V) \frac{d\xi}{dt} \quad (4)$$

where  $\xi$  is the body coordinate parallel to the baseline; see Figure 1. The last term on the right-hand side of Equation (4) takes into account the variation of the section added mass along the hull. This contribution can be visualized by considering the 2-D flow plane as a substantive surface moving past the body with velocity  $U = -d\xi/dt$  tangent to the baseline. As the surface moves past the body, the section geometry in the moving surface may change with a resultant change in added mass. This term exists even in steady-state conditions and is the lift-producing factor in low-aspect-ratio theory.

The added mass of a section with fully wetted chines has not been developed to the same extent as the V wedge. In steady-state planing problems such as those of Shuford,<sup>4</sup>

the crossflow is treated as a Helmholtz-type flow in which the Bobyleff results are used for estimating drag coefficients. Helmholtz flows are applicable only to steady-state conditions; so, it is assumed that the added mass for the fully wetted chine flow can be determined from Equation (3) using the value of the half-beam at the chine. In using the Shuford approach, it is assumed that the crossflow drag coefficient for a V-section is equal to the drag of a flat plate ( $C_{D,c} = 1.0$ ) corrected by the Bobyleff flow coefficient approximated by  $\cos \beta$ , i.e.

$$C_{D,c} = 1.0 \cos \beta \quad (5)$$

The Bobyleff flow coefficient is the theoretical ratio of the pressure on a V-section to that experienced by a flat plate for a Helmholtz-type flow.

The same approximation is used for estimating the drag coefficient for nonwetted chine sections, using the instantaneous value of the half-beam at the free surface.

An additional force acting on the body is the buoyancy force  $f_B$ . This force is assumed herein to act in the vertical direction and to be equal to the equivalent static buoyancy force multiplied by a correction factor, i.e.

$$f_B = -a \rho g(A) \quad (6)$$

where  $A$  is the cross-sectional area of the section, and  $a$  is a correction factor.

The full amount of the static buoyancy is not realized because at planing speeds the water separates from the transom and chines, reducing the pressure at these locations to atmospheric or less than the equivalent hydrostatic pressure. A greater reduction is realized in the buoyancy moment because of the corresponding shift in the center of pressure. Shuford<sup>4</sup> in his work on steady-state planing recommended a factor of one-half to obtain the correct buoyancy force. In the following computations, the buoyancy force was corrected by a factor of one-half, i.e.,  $a = 1/2$ . The buoyancy moment, computed as the static buoyancy force multiplied by its corresponding moment arm, was corrected by an additional factor of one-half to obtain the proper mean-trim angles.

Equation (2) is a synthesis of several idealized flow conditions combined in an empirical manner. In all of these flows, it is assumed that the net relative movement of the fluid past the body is in an upward direction. This condition may not always be met in the case of unsteady planing in waves. Closer scrutiny will be required to determine what limitations will be imposed upon the problem as formulated and/or what modifications will be required to improve the formulation.

## TOTAL HYDRODYNAMIC FORCE AND MOMENT

The total normal hydrodynamic force acting on the body is obtained by integrating the stripwise, 2-D, hydrodynamic force given by Equations (2) and (6) over the wetted length  $\xi$  of the body. A body coordinate system  $(\xi, \zeta)$  with its origin at CG and the  $\xi$  axis pointing forward parallel to the baseline of the body is defined in Figure 1 to facilitate this integration. The hydrodynamic force acting in the vertical or  $z$  direction of the fixed integral coordinate system is given by

$$\begin{aligned}
 -N \cos \theta &= F_z(t) = \int_{\xi} f \cos \theta d\xi + \int_{\xi} f_B d\xi \\
 &= - \left[ \int_{\xi} \{ m_a(\xi, t) \dot{V}(\xi, t) + \dot{m}_a(\xi, t) V(\xi, t) \right. \\
 &\quad - U(\xi, t) \frac{\partial}{\partial \xi} [m_a(\xi, t) V(\xi, t)] \\
 &\quad \left. + C_{D,c}(\xi, t) \rho b(\xi, t) V^2(\xi, t) \} \cos \theta d\xi \right. \\
 &\quad \left. + \rho g A d\xi \right] \quad (7)
 \end{aligned}$$

where the integration is taken over the instantaneous wetted length. Similarly the force  $F_x$  acting in the horizontal or  $x$  direction is given by

$$\begin{aligned}
 F_x &= \int_{\xi} f \sin \theta d\xi \\
 &= - \int \{ m_a(\xi, t) \dot{V}(\xi, t) + \dot{m}_a(\xi, t) V(\xi, t) \\
 &\quad - U(\xi, t) \frac{\partial}{\partial \xi} [m_a(\xi, t) V(\xi, t)] \\
 &\quad + C_{D,c}(\xi, t) \rho b(\xi, t) V^2(\xi, t) \} \sin \theta d\xi \quad (8)
 \end{aligned}$$

Wave forces are obtained by neglecting diffraction and assuming that the wave excitation is caused both by the geometrical properties of the wave, altering the wetted length and draft of the craft, and by the vertical component of the wave orbital velocity at the surface  $w_z$ , altering the normal velocity  $V$ . The horizontal component of orbital velocity is neglected.

since it is assumed small in comparison with the forward speed  $\dot{x}_{CG}$ . The velocities U and V may then be written as

$$\begin{aligned} U &= \dot{x}_{CG} \cos \theta - (\dot{z}_{CG} - w_z) \sin \theta \\ V &= \dot{x}_{CG} \sin \theta - \dot{\theta} \xi + (\dot{z}_{CG} - w_z) \cos \theta \end{aligned} \quad (9)$$

The depth of submergence h of the body at any point P( $\xi, \zeta$ ) may be determined by

$$h = z_{CG} - \xi \sin \theta + \zeta \cos \theta - r \quad (10)$$

where r is the instantaneous value of the wave elevation directly above the point.

For regular head waves the wave elevation for a linear deepwater wave is

$$r = r_0 \cos k(x + ct) \quad (11)$$

where  $r_0$  is the wave amplitude

$k$  is the wave number

$c$  is the wave celerity.

At point P( $\xi, \zeta$ )

$$x = x_{CG} + \xi \cos \theta + \zeta \sin \theta \quad (12)$$

$$\text{where } x_{CG} = \int_0^t \dot{x}_{CG} dt$$

The hydrodynamic moment  $F_\theta$  about CG is obtained in a similar manner by integrating over the wetted length the product of the normal force per unit length and the corresponding moment arm.

$$\begin{aligned}
F_\theta &= - \int_Q f(\xi, t) \xi d\xi - \int_Q I_b \cos \theta \xi d\xi \\
&= \int_Q \left\{ m_a(\xi, t) \dot{V}(\xi, t) + \dot{m}_a(\xi, t) V(\xi, t) \right. \\
&\quad - U(\xi, t) \frac{\partial}{\partial \xi} (m_a(\xi, t) V(\xi, t)) + C_{D,C}(\xi, t) \rho b(\xi, t) V^2(\xi, t) \\
&\quad \left. + a \rho g A \cos \theta \right\} \xi d\xi \quad (13)
\end{aligned}$$

## EQUATIONS OF MOTION, GENERAL

Integrating the first term in Equations (7), (8), and (13) provides hydrodynamic forces and moments proportional to acceleration of the motion. These can be combined with the inertial terms of the rigid body to give the following equation of motion

$$\begin{aligned}
&(M + M_a \sin^2 \theta) \ddot{x}_{CG} + (M_a \sin \theta \cos \theta) \ddot{z}_{CG} - (Q_a \sin \theta) \ddot{\theta} \\
&= T_x + F'_x - D \cos \theta \quad (14) \\
&(M_a \sin \theta \cos \theta) \ddot{x}_{CG} + (M + M_a \cos^2 \theta) \ddot{z}_{CG} - (Q_a \cos \theta) \ddot{\theta} \\
&= T_z + F'_z + D \sin \theta + W \\
&-(Q_a \sin \theta) \ddot{x}_{CG} - (Q_a \cos \theta) \ddot{z}_{CG} + (I + I_a) \ddot{\theta} \\
&= F'_\theta - D x_d + T x_p
\end{aligned}$$

$$\text{where } M_a(t) = \int_Q m_a(\xi, t) d\xi$$

$$Q_a(t) = \int_Q m_a(\xi, t) \xi d\xi$$

$$I_a(t) = \int_Q m_a(\xi, t) \xi^2 d\xi$$

$$F'_x = F_x - \{ -(M_a \sin^2 \theta) \ddot{x}_{CG} - (M_a \sin \theta \cos \theta) \ddot{z}_{CG} + (Q_a \sin \theta) \ddot{\theta} \}$$

$$F'_z = F_z - \{ \text{appropriate acceleration terms} \}$$

$$F'_\theta = F_\theta - \{ \text{appropriate acceleration terms} \}.$$

A detailed evaluation of the integral expressions for the hydrodynamic forces and moments is provided in Appendix A.

The solution to Equation (14) is cumbersome; however, it can be accomplished using standard numerical techniques. Introducing the state vector  $\{x_1, x_2, x_3, x_4, x_5, x_6\}$  where  $x_1 = \dot{y}_{CG}$

$$x_2 = \dot{z}_{CG}$$

$$x_3 = \dot{\theta}$$

$$x_4 = x_{CG}$$

$$x_5 = z_{CG}$$

$$x_6 = \theta$$

Equation (14) can be rewritten, using matrix algebra, as

$$A\vec{x} = \vec{g} \quad (15)$$

so that

$$\vec{x} = A^{-1}\vec{g} \quad (16)$$

where  $A^{-1}$  is inverse of the inertial matrix A. Equation (16) is now in a form that lends itself to integration by using a numerical method such as the Runge-Kutta-Merson integration routine.

#### EQUATIONS OF MOTION, SIMPLIFIED FOR CONSTANT SPEED

Assuming that the perturbation velocities in the forward direction are small in comparison to the speed of the craft, the equations of motion may be further simplified by neglecting the perturbations and setting the forward velocity equal to a constant, i.e.

$$\dot{x}_{CG} = \text{CONSTANT}$$

If it is also assumed that the thrust and drag forces are small in comparison to the hydrodynamic forces and that they are acting through the center of gravity, the equations of motion may be written as

$$\ddot{x}_{CG} = 0$$

$$(M + M_a \cos^2 \theta) \ddot{z}_{CG} - (Q_a \cos \theta) \ddot{\theta} = F_z' + W$$

$$-(Q_a \cos \theta) \ddot{z}_{CG} + (I + I_a) \ddot{\theta} = F_\theta'$$

These equations also represent the case of the craft (model) being towed through CG at CONSTANT speed. Based upon the previously described equations of motion, a computer program has been written in FORTRAN language to compute the motions of a prismatic body, planing in regular head waves at high speed. A listing of the program along with the appropriate flow chart is presented in Appendix B. The listing contains reference to thrust and drag terms; however, they have no significance, except to provide a starting point for possible updating of the program to include these terms in the future.

### COMPARISON OF COMPUTED RESULTS WITH EXPERIMENTS

Computations of pitch and heave motions and heave and bow accelerations were made, using the computer program for comparison with the experimental results of Fridsma.<sup>5</sup> Fridsma tested a series of constant-deadrise models of various lengths in regular waves to define the effects of deadrise, trim, loading, speed, length-to-beam ratio and wave proportions on the added resistance, heave and pitch motions, and impact accelerations at the bow and center of gravity. Figure 3 shows the lines of the prismatic models. The models were towed at CG with a system that permitted freedom in surge. The computer program simulates the model being towed at constant speed with CG at the baseline.

Table 1 presents some characteristics of the model and experimental conditions for which comparisons were made. Most of the comparisons have been made at a speed-to-length ratio  $V/\sqrt{L}$  of 6.0 where the mathematical model is expected to be most representative. A limited comparison has also been made at  $V/\sqrt{L} = 4.0$ ; however, no comparison has been made at  $V/\sqrt{L} = 2.0$ . At this speed, the model (or craft) operates in the displacement mode for which the mathematical formulation is not valid.

The average computer run corresponded to 10-second, real-time, model scale; however, only the last 2 seconds were considered free of transient effects. An example of the computer time histories of pitch and heave motions is shown in Figure 4. Although the motions are periodic, they are not perfectly sinusoidal; consequently, in determining phase relationship, the peak, positive-pitch value (bow up) and the peak, negative-heave value (maximum upward position of CG) were used as reference points. There was a difference when the opposite peaks were used.

**TABLE I - MODEL CHARACTERISTICS AND WAVE  
CONDITIONS FOR COMPUTATIONS**

Corresponding time histories of bow and CG accelerations are shown in Figure 5. The bow acceleration was computed at Station 0. As can be seen in these plots, the impact accelerations ranged in magnitude from cycle to cycle. The maximum impact (or negative value) acceleration computed during the final 2 seconds of run was used in the comparisons with experimental values. In some instances, particularly near resonance, the maximum impact acceleration was more than twice the average impact value.

Figure 6 shows a comparison of variation of computed and experimental pitch and heave motion with wave height for the 20-degree deadrise model in a 15-foot wavelength and for a speed-to-length ratio of 6.0. Figure 7 shows the corresponding impact acceleration at the bow and CG. The computed results closely follow the experimental data, except for CG acceleration at the extreme wave height condition, where the computed value is apparently much lower. Experimental data show that the model was leaving the water at this wave-height condition. The computer model did not leave the water but came very close:

see Figure 8. Figure 8 is a trajectory of the computer model relative to the wave for a selected cycle of motion. The computer model behaves very much as expected. On the left-hand side of the figure, the craft is planing down the crest of the wave and, as it approaches the wave trough, comes very close to leaving the water before slamming and submerging itself deeply into the front of the oncoming wave crest.

Figures 9 through 14 show comparisons of the computed and experimental pitch and heave motions at  $V/\sqrt{L} = 6.0$  through a range of wavelengths and at a constant wave height of 2.54 centimeters (1 inch) for deadrise models with 10, 20, and 30 degrees. The data have been plotted with respect to the coefficient  $C_\lambda$ , defined by Fridsma as  $L/\lambda [C_\Delta/(L/2b)^2]^{1/3}$ . Note that in our notation,  $b$  is the half-beam.

Comparisons of heave and pitch for the 10-degree deadrise model shown in Figures 9 and 10, respectively, show excellent results. The computer model accurately predicts the secondary peaks in the pitch and heave responses at  $C_\lambda = 0.19$ . At this condition, the physical experimental model rebounds so as to fly over alternate waves. The computer model oscillates at half the wave-encounter frequency and comes close to leaving the water at alternate encounters with the wave. It does not quite leave the water to fly over alternate wave crests; nonetheless, it is a good representation of the actual motion.

The heave and pitch comparison for the 20-degree deadrise model at  $V/\sqrt{L} = 6.0$  is also excellent as can be seen in Figures 11 and 12, respectively. No experimental phase data for the condition were reported for  $C_\lambda$  greater than 0.072; however, extrapolated results (not shown) are in line with the computed results. The pitch and heave results shown in Figures 13 and 14 for the 30-degree deadrise model are good; however, responses at  $C_\lambda = 0.048$  and  $C_\lambda = 0.072$  are higher than the experimental results.

For practical considerations a computational scheme for planing boat motions should be valid for a range from approximately  $V/\sqrt{L} = 4.0$  to  $V/\sqrt{L} = 6.0$ . Computations of the motions were made for  $V/\sqrt{L} = 4.0$  for the 20-degree deadrise model; see Figures 15 and 16. Again the comparison of the computed heave and pitch response with experimental results is excellent.

Comparisons of the computed and experimental impact accelerations (or largest negative values) are presented in Figures 17 through 20. Figures 17 and 18 show bow and CG accelerations for the 10-degree deadrise model; Figure 19 shows similar results for the 20-degree deadrise model. Figure 20 shows the results for the 30-degree deadrise model. In all cases, the comparison appears to be fair to good. In the shorter wavelengths,  $\lambda/L = 1.0$  and  $\lambda/L = 1.5$ , the computed accelerations are higher than the corresponding experimental values. This is most pronounced for the 10-degree deadrise angle model.

## **CONCLUSIONS AND RECOMMENDATIONS**

A mathematical model of a craft having a constant deadrise angle, planing in regular waves, has been formulated using a modified low-aspect-ratio or strip theory. It was assumed that the wavelengths were long in comparison to the craft length and that the wave slopes were small. The coefficients in the equations of motion were determined by a combination of theoretical and empirical relationships.

A simplified version for the case of a craft or model being towed at constant speed was programmed for computations on a digital computer, and the results were compared with existing experimental data.

The comparison of the computed pitch and heave motions and phase angles with the corresponding experimental data gave remarkably satisfying results. Comparison of the bow and CG accelerations was fair to good.

In summary, the previously described mathematical model appears to be a valid representation of a planing craft in waves for the specific craft geometry and wave conditions considered.

To make the computer program more valuable to the designer the following additional work is recommended:

1. Improve estimates of hydrodynamic coefficients to obtain better acceleration data and to include more complicated ship geometry.
2. Determine added resistance in waves.
3. Include freedom to surge and to add components of propulsion.
4. Extend to the case of irregular waves.

## APPENDIX A EVALUATION OF HYDRODYNAMIC FORCE AND MOMENT INTEGRALS

The hydrodynamic force the craft experiences in the vertical direction as derived in the text is:

$$F_z = - \int_{\ell} \left\{ m_a \dot{V} - U \frac{\partial m_a V}{\partial \xi} + \dot{m}_a V + C_D \rho b V^2 \right\} \cos \theta d\xi + \int_{\ell} a \rho g A d\xi$$

where  $U = \dot{x}_{CG} \cos \theta - (\dot{z} - w_z) \sin \theta$

and

$$V = \ddot{x}_{CG} \sin \theta + (\dot{z} - w_z) \cos \theta - \dot{\theta} \xi$$

Another force acting in the vertical direction is the weight of the craft.

The first two terms of the integral are evaluated by making the substitutions

$$\begin{aligned} \dot{V} &= \ddot{x}_{CG} \sin \theta - \ddot{\theta} \xi + \ddot{z}_{CG} \cos \theta - \dot{w}_z \cos \theta \\ &\quad + \dot{\theta} (\dot{x}_{CG} \cos \theta - \dot{z}_{CG} \sin \theta) + w_z \dot{\theta} \sin \theta \end{aligned}$$

$$\frac{\partial V}{\partial \xi} = -\dot{\theta} - \frac{\partial w_z}{\partial \xi} \cos \theta$$

$$\frac{\partial U}{\partial \xi} = \frac{\partial w_z}{\partial \xi} \sin \theta$$

$$\frac{d w_z}{dt} = \dot{w}_z - U \frac{\partial w_z}{\partial \xi}$$

and noting that

$$\int_{\ell} UV \frac{\partial m_a}{\partial \xi} d\xi = -UV m_a \Big|_{stern} - \int_{\ell} m_a \frac{\partial UV}{\partial \xi} d\xi$$

Using the previously described substitutions, the force becomes

~~Preceding Page BLANK~~

$$F_z = \left\{ -M_a \cos \theta \ddot{z}_{CG} - M_a \sin \theta \ddot{x}_{CG} + Q_a \ddot{\theta} + M_a \dot{\theta} (\dot{z}_{CG} \sin \theta - \dot{x}_{CG} \cos \theta) \right. \\ \left. + \int_{\xi} m_a \frac{dw_z}{dt} \cos \theta d\xi - \int_{\xi} m_a w_z \dot{\theta} \sin \theta d\xi \right. \\ \left. - \int_{\xi} m_a V \frac{\partial w_z}{\partial \xi} \sin \theta d\xi + \int_{\xi} m_a U \frac{\partial w_z}{\partial \xi} \cos \theta d\xi \right. \\ \left. - UV m_a \Big|_{stern} - \int_{\xi} V \dot{m}_a d\xi - \rho \int_{\xi} C_{D,c} b V^2 d\xi \right\} \cos \theta \\ + \int_{\xi} a_{pg} A dt$$

where  $M_a = \int_{\xi} m_a d\xi$

and

$$Q_a = \int_{\xi} m_a \dot{\theta} d\xi$$

This is essentially the form in which the integrals have been computed in the program.

The rate of change of the sectional added mass in the third term of the integral expression is derived by relating it to the rate of change of depth of fluid penetration of the section. The added mass of a section is assumed to be equal to

$$m_a = k_a \pi / 2 \rho b^2$$

for which the time derivative is

$$\dot{m}_a = k_a \pi \rho b \dot{b}$$

where  $b$  is the instantaneous half-beam of the section, and  $k_a$  is an added-mass coefficient, assumed to be constant. A value of  $k_a = 1.0$  was used in the computations contained in this report. For sections with constant deadrise, which is an imposed limitation of this work, the half-beam is related to the depth of penetration by

$$b = d \cot \beta$$

where  $d$  is depth of penetration, and  $\beta$  is deadrise angle.

Taking into account the effect of water pileup, the effective depth of penetration  $d_e$  is, according to Wagner

$$d_e = \pi/2 d$$

and

$$b = d_e \cot \beta = \pi/2 d \cot \beta$$

where  $\pi/2$  is the factor by which the wedge immersion is increased by the pileup. Using this expression for the half-beam, the rate of change of sectional added mass becomes

$$\dot{m}_a = k \pi \rho b (\pi/2 \cot \beta) d$$

This expression is valid for penetration of the section up to the chine. When the immersion exceeds the chine, the sectional added mass is assumed to be constant, i.e.,

$$m_a = k \pi/2 \rho b_{max}^2$$
$$\dot{m}_a = 0$$

where  $b_{max}$  is the half-beam at chine.

The submergence of a section in terms of the motions is given by

$$h = z - r$$

where  $z = z_{CG} - \xi \sin \theta + \zeta \cos \theta$

$$r = r_0 \cos \{\psi (x_{CG} + \xi \cos \theta + \zeta \sin \theta) + \omega t\}$$

For wavelengths which are long in comparison to the draft and for small wave slopes, the immersion of a section measured perpendicular to the baseline is approximately

$$d \approx \frac{z - r}{\cos \theta - v \sin \theta}$$

where  $v$  = wave slope

The rate change of submergence  $d$  is given by

$$\dot{d} = \frac{\dot{z} - \dot{r}}{\cos \theta - v \sin \theta} + \frac{(z - r)}{(\cos \theta - v \sin \theta)^2} \cdot \frac{\partial(\cos \theta - v \sin \theta)}{\partial t}$$

Since immersion ( $z - r$ ) is always small in the valid range of the previously described expression, the relationship can be further simplified to

$$\dot{d} \approx \frac{\dot{z} - \dot{r}}{\cos \theta - v \sin \theta}$$

and

$$\dot{m}_a \approx k_a \pi \rho b (\pi/2 \cot \beta) \frac{(\dot{z} - \dot{r})}{\cos \theta - v \sin \theta}$$

The expansion of the integral expression for the hydrodynamic moment in pitch follows the procedure used for the vertical force. The results are summarized as follows

$$\begin{aligned} F_\theta = & -I_a \ddot{\theta} + Q_a \cos \theta \ddot{z}_{CG} - Q_a \dot{\theta} (\dot{z}_{CG} \sin \theta - \dot{x}_{CG} \cos \theta) \\ & - \int_Q m_a \cos \theta \frac{dw_z}{dt} \xi d\xi + \int_Q m_a \dot{\theta} \sin \theta w_z \xi d\xi \\ & + \int_Q V \dot{m}_a \xi d\xi + \int_Q \rho C_D b V^2 \xi d\xi \\ & + m_a U V \xi \Big|_{stern} + \int_Q m_a V U d\xi \\ & + \int_Q m_a V \frac{\partial w_z}{\partial \xi} \sin \theta \xi d\xi \\ & - \int_Q m_a U \frac{\partial w_z}{\partial \xi} \cos \theta \xi d\xi \\ & + \int_Q a \rho g A \cos \theta \xi d\xi \end{aligned}$$

The only additional moments are the buoyancy moments. All other moments are considered to be zero for the specific problem considered in this report.

## APPENDIX B COMPUTER PROGRAM DESCRIPTIONS

### OVERVIEW

The equations of motions developed in the previous sections of this report have been solved by means of digital computer programs. Two major programs have been developed: the first (MAIN) solves the equations of motion using the Runge-Kutta-Merson integration algorithm and generates time histories that are stored on the system disk. The second (PLTHSP) generates California Computer Products Company (CALCOMP) pen plots from the disk files. All programs were designed to operate on the Control Data Corporation computer system, located at the David W. Taylor Naval Ship Research and Development Center in Carderock, Md.

Descriptions of input data required to execute the programs, job control cards, and programs follow. Sufficient detail is presented for this appendix to serve as a manual for use and maintenance.

### JOB CONTROL CARDS FOR PROGRAM MAIN

Job control cards for program MAIN which computes time histories of the motion variables, are described as follows. If CALCOMP plots are not desired, TAPES need not be cataloged.

| Job Control Language Card:               | <u>Comment</u>                          |
|--|---|
| Job Card                                 | Standard facility card                  |
| Charge Card                              | Standard facility card                  |
| REQUEST,TAPE9,*PF.                       | Reserves space for CALCOMP plot data    |
| REQUEST,TAPE2,*PF.                       | Print output file 1 request             |
| REQUEST,TAPE4,*PF.                       | Print output file 2 request             |
| ATTACH,BINAR,SEFZARNICKNEWB,<br>ID=XXXX. | Attaches binary run file                |
| ATTACH,NSRDC.                            | Attaches library routines               |
| LDSET(LIB=NSRDC).                        | Loads library routines                  |
| BINAR.                                   | Loads and executes run file             |
| REWIND,TAPE2.                            | Rewinds time-history files for printing |
| REWIND,TAPE4.                            |   |
| COPY(TAPE2,OUTPUT)                       | Prints time-history file                |
| COPY(TAPE4,OUTPUT)                       | Prints time-history file                |

| Job Control Language Card:                 | <u>Comment</u>  |
|--|---|
| CATALOG,TAPE9, SEFZARNICKDATA..., ID=XXXX. | Catalogues file for plot.<br>(SEFZARNICKDATA CAN BE ANY NAME) |
| 7/8/9 END OF RECORD                        |   |
| DATA CARDS (1-5)                           |   |
| 6/7/8/9 END OF FILE                        |   |

### **INPUT DATA CARDS FOR PROGRAM MAIN**

Input data used by program MAIN are read from data cards in NAMELIST and in standard format. A description of the FORTRAN symbols appearing in NAMELIST follows. For simplicity in the text that follows, it is assumed that NAMELIST input occupies only one card. More cards can be used if necessary.

#### **Card 1(NAMELIST FORMAT, /      / )**

|        |   |
|--------|---|
| A      | The absolute error for KUTMER (six values)  |
| NPRINT | If = 1, print normal output<br>If = 2, matrix, inverse matrix, F-column matrix, and KUTMER results<br>If = 3, integral results<br>If = 4, calculated values constant for given input values |
| NPLOT  | If = 0, no plot<br>If = 1, printer plot of results  |
| END    | Number of runs to be made   |
| W      | Weight of craft in pounds   |
| BL     | Boat length in feet   |
| TZ     | Thrust component in z direction   |
| TX     | Thrust component in x direction   |
| XECG   | Distance from center of gravity to center of pressure for drag force in feet  |
| XP     | Moment arm of propeller thrust  |
| XD     | Distance from center of gravity to center   |
| DRAG   | Friction for drag force   |
| RO     | Wave height   |
| LAMBDA | Wavelength  |
| RG     | Radius of gyration in feet  |
| T      | Propeller thrust in pounds  |
| GAMMA  | Propeller thrust angle in degrees   |

**Card 1 (continued)**

|         |   |
|---------|---|
| ECG     | Longitudinal center of gravity                                |
| NCG     | Vertical center of gravity, nondimensionalized by ship length |
| KAR     | Added-mass coefficient  |
| BETA(I) | Dead-rise angle in degrees                                    |
| EST(I)  | Station position in feet                                      |
| NUM     | Number of stations  |
| XA      | Initial time  |
| XE      | Stop time   |
| HMIN    | Minimum step size   |
| HMAX    | Maximum step size   |
| EPS     | Error criterion   |

**Card 2 (Format 8F10.0)**

|              |                    |
|--------------|--------------------|
| (X(1),I=1,6) | Initial conditions |
| X(1)         | Velocity           |
| X(2)         | Z                  |
| X(3)         | 0                  |
| X(4)         | X                  |
| X(5)         | Z                  |
| X(6)         | $\theta$ degrees   |

**Card 3 (8F10.0)**

|       |  |
|-------|--|
| START | Time to turn on (RMP) function (see page 48) |
| RISE  | Duration of RMP                              |

**Card 4 (8F10.0)**

|     |  |
|-----|--|
| TME | Time at which integration interval is to be changed* |
| HMX | New maximum interval size after TME                  |
| HMN | New minimum interval size for KUTMER to subdivide    |

---

\*If this option is not used set TME to stop time on run.

### **Card 5 (8F10.0)**

**PERCNT**      Percentage of boat length subtracted from longitudinal center of gravity to obtain X - point where acceleration computations are made

### **JOB CONTROL CARDS FOR PROGRAM PLTHSP**

Job control cards for program PLTHSP which generates CALCOMP plots of time histories computed by program MAIN are described in this section.

#### **Job Control Language Card:**

|   | <u>Comment</u>                                |
|---|---|
| Job Card                                  | Standard facility card                        |
| Charge Card                               | Standard facility card                        |
| REQUEST,TAPE7,HI.                         | Tape for CALCOMP plot data                    |
| VSN(TAPE7=CK0323).                        | Volume serial number of tape for CALCOMP plot |
| ATTACH,CALC936.                           | Attaches CALCOMP library routine              |
| ATTACH,BINAR,SFFZARNICKPLOTB,<br>ID=XXXX. | Attaches plot program run file                |
| LDSET(LIB=CALC936)                        | Loads CALCOMP library routines                |
| BINAR.                                    | Runs plot program                             |
| 7/8/9 END OF RECORD                       |   |
| DATA CARDS                                |   |
| 6/7/8/9 END OF FILE                       |   |

### **INPUT DATA CARDS FOR PROGRAM PLTHSP**

Two or three data cards are made ready by PLTHSP, depending on the options selected. Standard input format is employed. A description of the necessary data cards follows.

#### **Card 1 (8F10.0 Format)**

**XAXIS**      Length of x axis in inches  
**YAXISP**      Height of pitch component axis in inches  
**YAXISH**      Height of heave component axis in inches  
**HT**      Height of lettering in inches

#### **Card 2 (I10 Format)**

**IA**      If = 0, no plots for bow acceleration and center of gravity acceleration  
              If = 1, plots previously mentioned information

**Card 3 (8F10.0 Format) - Only Necessary If IA = 1.**

**YAXISB**      Height of bow acceleration axis in inches  
**YAXISC**      Height of CG acceleration axis in inches

### **PROGRAM MAIN**

Program MAIN reads all necessary input data from cards, sets up initial values, computes constants, calls KUTMER to determine the state variables at TIME for the period from XA to XE in increments of HMAX. A table state variables is created for every PTIME-th value. The values for  $\lambda/H$  and  $\theta_p/2\pi H/\lambda$  are calculated and printed. If the plot option is on, a printer plot will be produced.

### **Subroutine COMPUT(X)**

This routine computes pitch moment NL and lift force FL, excluding added mass terms, using values of integrals computed in subroutine FUNCT. The argument X contains the state vector.

### **Subroutine DAUX**

This subroutine is called from KUTMER or EULER. It determines the values of  $m_w$ , b, and  $b_1^*$ , based on the following equations

$$h_w(l) = z_{CG} - \xi(l) \sin \theta + \zeta(l) \cos \theta - r(l)$$

$$\text{where } r(l) = r_0 \cos k [x_{CG} + \xi(l) \cos \theta + \zeta(l) \sin \theta + ct]$$

Then for

$$h_w(l) > 0,$$

$$d(l) = \frac{h_w(l)}{\cos \theta - (l) \sin \theta}$$

$$\text{where } V(l) = -r_0 k \sin \theta [x_{CG} + \xi(l) \cos \theta + (l) \sin \theta + ct]$$

If

$$d(l) \geq b_m(l) \tan(\beta(l) 2/\pi)$$

set

$$\begin{aligned}m_a(l) &= m_{amax}(l) \\b(l) &= b_m(l) \\b_l(l) &= 0 \\m_{amax}(l) &= k(l)(\rho/2)\pi b_m^2(l)\end{aligned}$$

if

$$d(l) < b_m(l) \tan(\beta(l))(2/\pi)$$

set

$$\begin{aligned}b(l) &= d(l) \cot(\beta(l))(\pi/2) \\b_l(l) &= b(l) \\m_a(l) &= k_a(l)(\rho/2)\pi b^2(l)\end{aligned}$$

for

$$\begin{aligned}h_w(l) &\leq 0 \\m_a(l) &= 0, \quad b(l) = 0, \quad b_l(l) = 0\end{aligned}$$

This subroutine then calls FUNCT which in turn calls COMPUT to determine the values of  $N_L$  and  $F_L$ , the lift force and moment. The values of  $N_L$  and  $F_L$  are used to compute the following

$$\begin{aligned}F_1 &= T_x + F_L \sin \theta - D \cos \theta \\F_2 &= T_z + F_L \cos \theta + D \sin \theta + W \\F_3 &= N_L - D x_d + T x_p\end{aligned}$$

---

\* $b_l$  array is set up for integrations for portion of hull for which chine is not immersed.

The mass inertia matrix is

$$A_{11} = M + M_a \sin^2 \theta$$

$$A_{12} = M_a \sin \theta \cos \theta$$

$$A_{13} = -Q_a \sin \theta$$

$$A_{21} = A_{12}$$

$$A_{22} = M + M_a \cos^2 \theta$$

$$A_{23} = -Q_a \cos \theta$$

$$A_{31} = A_{13}$$

$$A_{32} = A_{23}$$

$$A_{33} = I + I_a$$

The matrix is inverted by the system routine MATINS. The inverted matrix is then used to solve the following equations which determine the state vectors.

$$\ddot{x}_{CG} = A_{11}^{-1} F_1 + A_{12}^{-1} F_2 + A_{13}^{-1} F_3$$

$$\ddot{z}_{CG} = A_{21}^{-1} F_1 + A_{22}^{-1} F_2 + A_{23}^{-1} F_3$$

$$\ddot{\theta} = A_{31}^{-1} F_1 + A_{32}^{-1} F_2 + A_{33}^{-1} F_3$$

#### Subroutine FUNCT (X)

This routine evaluates various integrals appearing in the force and moment mathematical models. The integrals are evaluated, using a trapezoidal integration algorithm. The argument x contains the state vector. A list of integrals that are evaluated is presented.

$$\begin{array}{ll}
\int_{\xi} m_a d\xi & \int_{\xi} m_a \xi d\xi \\
\int_{\xi} m_a \xi^2 d\xi & \int_{\xi} m_a U V d\xi \\
\int_{\xi} m_a w_z d\xi & \int_{\xi} m_a w_z \xi d\xi \\
\int_{\xi} m_a \frac{dw_z}{dt} d\xi & \int_{\xi} m_a \frac{dw_z}{dt} \xi d\xi \\
\int_{\xi} m_a V \frac{\partial w_z}{\partial \xi} d\xi & \int_{\xi} m_a V \frac{\partial w_z}{\partial \xi} \xi d\xi \\
\int_{\xi} m_a U \frac{\partial w_z}{\partial \xi} d\xi & \int_{\xi} m_a U \frac{\partial w_z}{\partial \xi} \xi d\xi \\
\int_{\xi} m_a V d\xi & \int_{\xi} m_a V \xi d\xi \\
\int_{\xi} b V^2 d\xi & \int_{\xi} b V^2 \xi d\xi \\
\int_{\xi} b \left( h - \frac{b}{2} \tan \beta \right) d\xi & \int_{\xi} b \left( h - \frac{b}{2} \tan \beta \right) \xi d\xi
\end{array}$$

### Subroutine INPUT

This routine reads in NAMELIST/HSP/ which contains the initial data concerning the craft and sea conditions pertinent to all the runs to be made. It is set up so that most of the data are given default values by means of data statements in subroutine INPUT. These data statements can be overridden during execution by reading values in on cards. For further explanation of the specific variables see section on the input data cards.

This routine also "initializes" constant such as  $\pi$ ,  $\rho$ , and  $g$ . It uses the input values to calculate the keel profile and planform arrays, NO and BM, wave constants, system mass and inertia, and maximum mass and depth of chine at each station.

### Subroutine KUTMER (NEQS, TIME, HMAX, X, EPSE, A, HMIN, FIRST)

This is a Runge-Kutta-Merson integration routine that is capable of changing the size of the interval over which it integrates to meet specified error criteria. It is therefore an

accurate method for a system that may oscillate more rapidly than the initial integration interval. A minimum step size prevents the routine from subdividing the interval indefinitely.

The input arguments are:

|       |  |
|-------|--|
| NEQS  | Number of dependent variables in the x array   |
| TIME  | Actual time (independent variable)   |
| HMAX  | Increment for which the solution is to be returned   |
| X     | Vector of dependent variables  |
| EPSE  | Relative error criteria specified for each component of x and used for the components of x less than the absolute value of A                                     |
| A     | Absolute error criteria  |
| HMIN  | Minimum step size allowed  |
| FIRST | Set to zero on first call; a value of 1 is assigned by KUTMER on subsequent calls for which the error criteria are satisfied, otherwise a value of 2 is assigned |

#### **Subroutine PLOT2 (F, FMIN, FMAX, NVAR, NFUN, N1, N, XC, DELX)**

Data stored in the two-dimensional array F are plotted, using the printer by subroutine PLOT2. As many as 26 different functions, having evenly spaced abscissa values, can be plotted. The output is written on Unit 6. A description of variables follows.

|      |   |
|------|---|
| F    | Array containing data to be plotted; the Jth point of the Ith function is stored in F(I,J)  |
| FMIN | An array of minimum functional values; the minimum of the Ith function is stored in FMIN(I) |
| FMAX | Same as FMIN only for maximum values  |
| NVAR | An array of titles for each function to be plotted  |
| NFUN | Number of functions to be plotted   |
| N1   | First dimension of array F  |
| N    | Number of points to be plotted  |
| XO   | First abscissa value  |
| DELX | Abscissa increment  |

#### **Subroutine PLOTER (FX, XA, HMAX, LAMBDA, IB, NWAVE)**

The routine initializes various values required to generate printer plots and computes pitch-and-heave ratios. The printer plots that are generated consists of pitch-and-heave time histories. A description of input variables follows.

|               |   |
|---------------|---|
| <b>FX</b>     | A two-dimensional array, containing time histories to be plotted                      |
| <b>XA</b>     | Initial time  |
| <b>HMAX</b>   | Time-interval increment; time interval between values in FX is given by<br>HMAX*PTIME |
| <b>LAMBDA</b> | Wavelength  |
| <b>IB</b>     | Number of values to be plotted  |
| <b>NWAVE</b>  | Position in FX at which wave is completely turned on                                  |

#### **Function RMP (T, START, RISE)**

The RMP is a function that calculates a value between 0 and 1 corresponding to time T, based on a straight line from time START with a value of 0 to time START plus RISE with a value of 1. It is used to lower the initial wave amplitude to avoid large transients at start of the computations.

The arguments are:

|              |   |
|--------------|---|
| <b>T</b>     | Actual time                                 |
| <b>START</b> | Time at which to begin the ramp from 0 to 1 |
| <b>RISE</b>  | Duration of rise from 0 to 1                |

The function reaches the value 1 at time START plus RISE, if the rise is 0.0, RMP will return a value of 0.5.

#### **Subroutine TRAP (F, DX, NPTS, ANS)**

This routine performs the evaluation of an integral using a trapezoidal approximation.

The argument variables are defined as follows:

|             |                                    |
|-------------|------------------------------------|
| <b>F</b>    | Array of integrand values          |
| <b>DX</b>   | Increments at which F is evaluated |
| <b>NPTS</b> | Number of values in F              |
| <b>ANS</b>  | Result, which is equal to          |

$$DX \left\{ \sum_{i=1}^{NPTS} F(i) - 0.5 [F(1) + F(NPTS)] \right\}$$

#### **PROGRAM PLTHSP**

This program uses a data file created by program MAIN to create CALCOMP plots. The data are read from logical Unit 9 and are rewritten on Unit 7 for CALCOMP input. Program PLTHSP sets the tape output unit equal to 7 and calls SUBROUTINE CALPHI to execute the plot procedures.

### **Subroutine CALPLT**

This subroutine manages all the I/O operations and performs the necessary calculations required to generate the plots. After reading the card data (two or three cards) subroutine READT is called to read the data file (Tape 9) created by program MAIN. The CALCOMP initializing routines are called next, after which a call to subroutine ESCALE calculates the necessary scaling factors. Subroutine EXAXIS is called next to determine the placement of the plot tick marks and identifying digits. The CALCOMP plot-generation subroutines are now called and, depending on the option defined by the IA parameter on card 2, plots of pitch and heave at the bow and CG location are generated as functions of time if IA = 1.

### **Subroutine EXAXIS**

The subroutine is analogous to the CALCOMP AXIS routine. The only exception is that the tick marks are not necessarily inch, and the height of the characters is defined by the input parameter HT. Function NDIGIT is called to determine the number of digits necessary to print an even increment of the plots functions on the axis.

### **Subroutine ESCALE, ADJUST, and FUNCTION UNIT**

These subroutines find the scale to be used on the plot axis. Function UNIT is called to determine the axis increment size after which subroutine ADJUST is called to extend the minimum (AMIN) and maximum (AMAX) values so that they are even multiples of the axis increments.

### **FUNCTION NDIGIT**

This function finds the number of digits necessary to print even increments of the function on the axis. Both the number of places in the entire number (NDIGIT) and the number of decimal places (ND) are determined, after which the value of each increment on the axis (ANUM) is calculated.

### **Subroutine READT**

This subroutine reads the data file created by program MAIN. Data file records are read until the message end of file is encountered. Each record is read in the same format as it was written in MAIN. The information is printed to allow the user to inspect the created file.

DTNSRDC ISSUES THREE TYPES OF REPORTS

1. DTNSRDC REPORTS, A FORMAL SERIES, CONTAIN INFORMATION OF PERMANENT TECHNICAL VALUE. THEY CARRY A CONSECUTIVE NUMERICAL IDENTIFICATION REGARDLESS OF THEIR CLASSIFICATION OR THE ORIGINATING DEPARTMENT.
2. DEPARTMENTAL REPORTS, A SEMIFORMAL SERIES, CONTAIN INFORMATION OF A PRELIMINARY, TEMPORARY, OR PROPRIETARY NATURE OR OF LIMITED INTEREST OR SIGNIFICANCE. THEY CARRY A DEPARTMENTAL ALPHANUMERICAL IDENTIFICATION.
3. TECHNICAL MEMORANDA, AN INFORMAL SERIES, CONTAIN TECHNICAL DOCUMENTATION OF LIMITED USE AND INTEREST. THEY ARE PRIMARILY WORKING PAPERS INTENDED FOR INTERNAL USE. THEY CARRY AN IDENTIFYING NUMBER WHICH INDICATES THEIR TYPE AND THE NUMERICAL CODE OF THE ORIGINATING DEPARTMENT. ANY DISTRIBUTION OUTSIDE DTNSRDC MUST BE APPROVED BY THE HEAD OF THE ORIGINATING DEPARTMENT ON A CASE-BY-CASE BASIS.
